Deployment models

IoT+Edge

- Process data *in situ* at the Edge
- Low latencies but
- Limited capabilities
- Difficulties in sharing data

IoT+Cloud

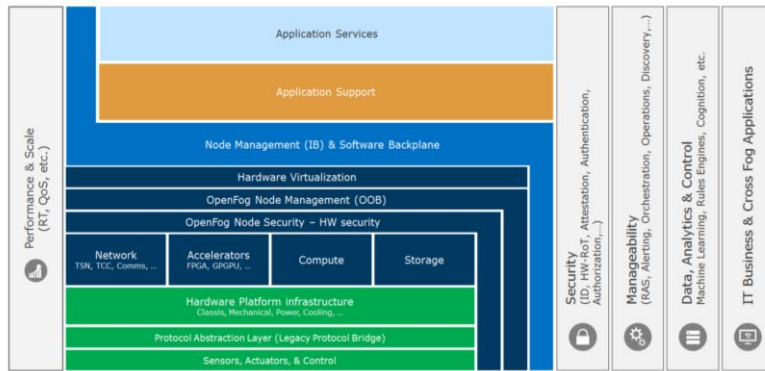

- Send data to Cloud for processing
- Huge computing power but
- Mandatory connectivity
- High latencies
- Bandwidth bottleneck

Fog Computing

Fog computing aims at extending the Cloud towards the IoT to better support **latency-sensitive** and **bandwidth-hungry** IoT applications

Fog Computing

«A system level horizontal architecture that distributes resources and services of **computing, storage, control** and **networking** anywhere **along the continuum from Cloud to Things**, thereby **accelerating** the velocity of **decision making**.»

Fog and IoT: An Overview of Research Opportunities

Mung Chiang, *Fellow, IEEE*, and Tao Zhang, *Fellow, IEEE*

Architecture is about functionality allocation [1]: deciding who does what and how to “glue” them back together. Unlike the more mature technology fields such as serial computation, digital communication, and the Internet, where strong and solid architectural foundation has been laid, we are still searching for architectural principles for many emerging systems and applications such as IoT, cyber-physical systems, and embedded artificial intelligence (AI). We need to make fundamental decisions ranging from where to compute and where to store data along the “cloud-to-things” continuum to how to map computation tasks into a substrate of heterogeneously capable and variably available nodes.

A blackboard with a wooden frame, containing two lines of white text. The text is written in a casual, handwritten style.

Fog computing?

Deploying apps through the Fog

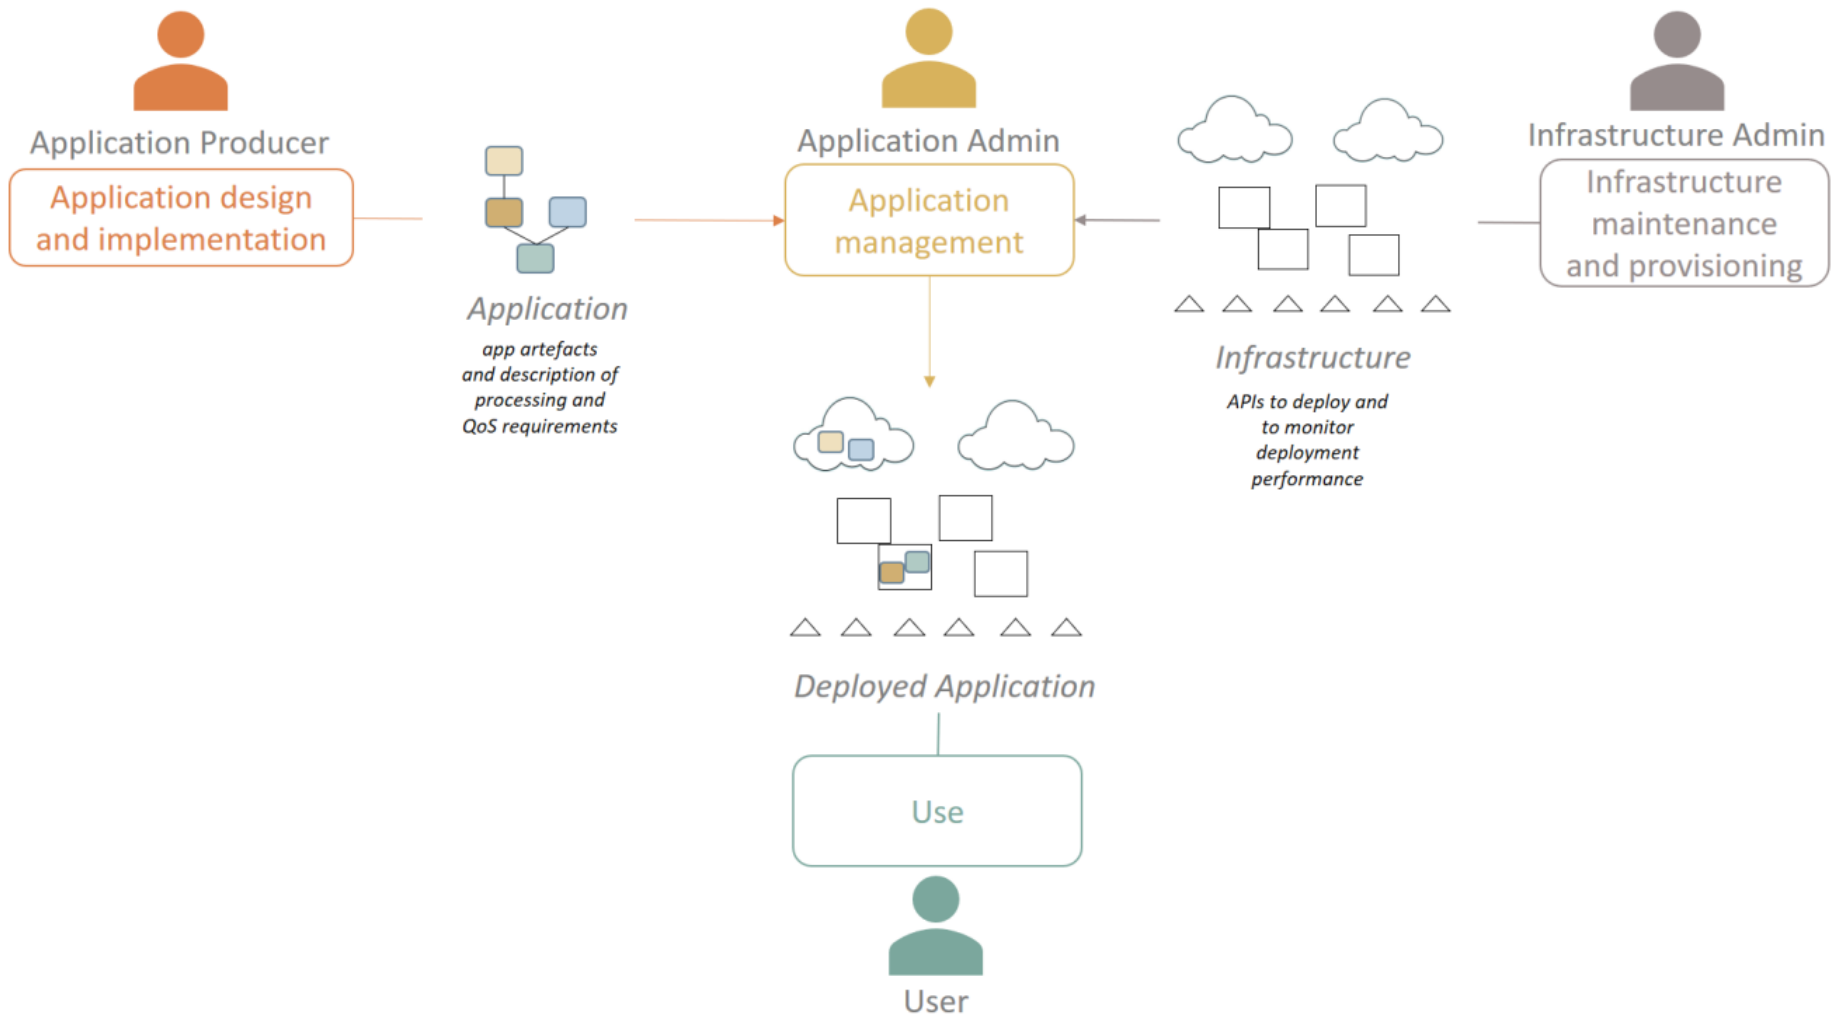

Deploying composite applications in a QoS- and context-aware manner over the continuum from Things to Cloud is challenging

App requirements	Fog infrastructure
------------------	--------------------

- | | |
|---|--|
| <ul style="list-style-type: none">• Hardware• Software• QoS | <ul style="list-style-type: none">• Heterogeneous• Large• Dynamic* |
|---|--|

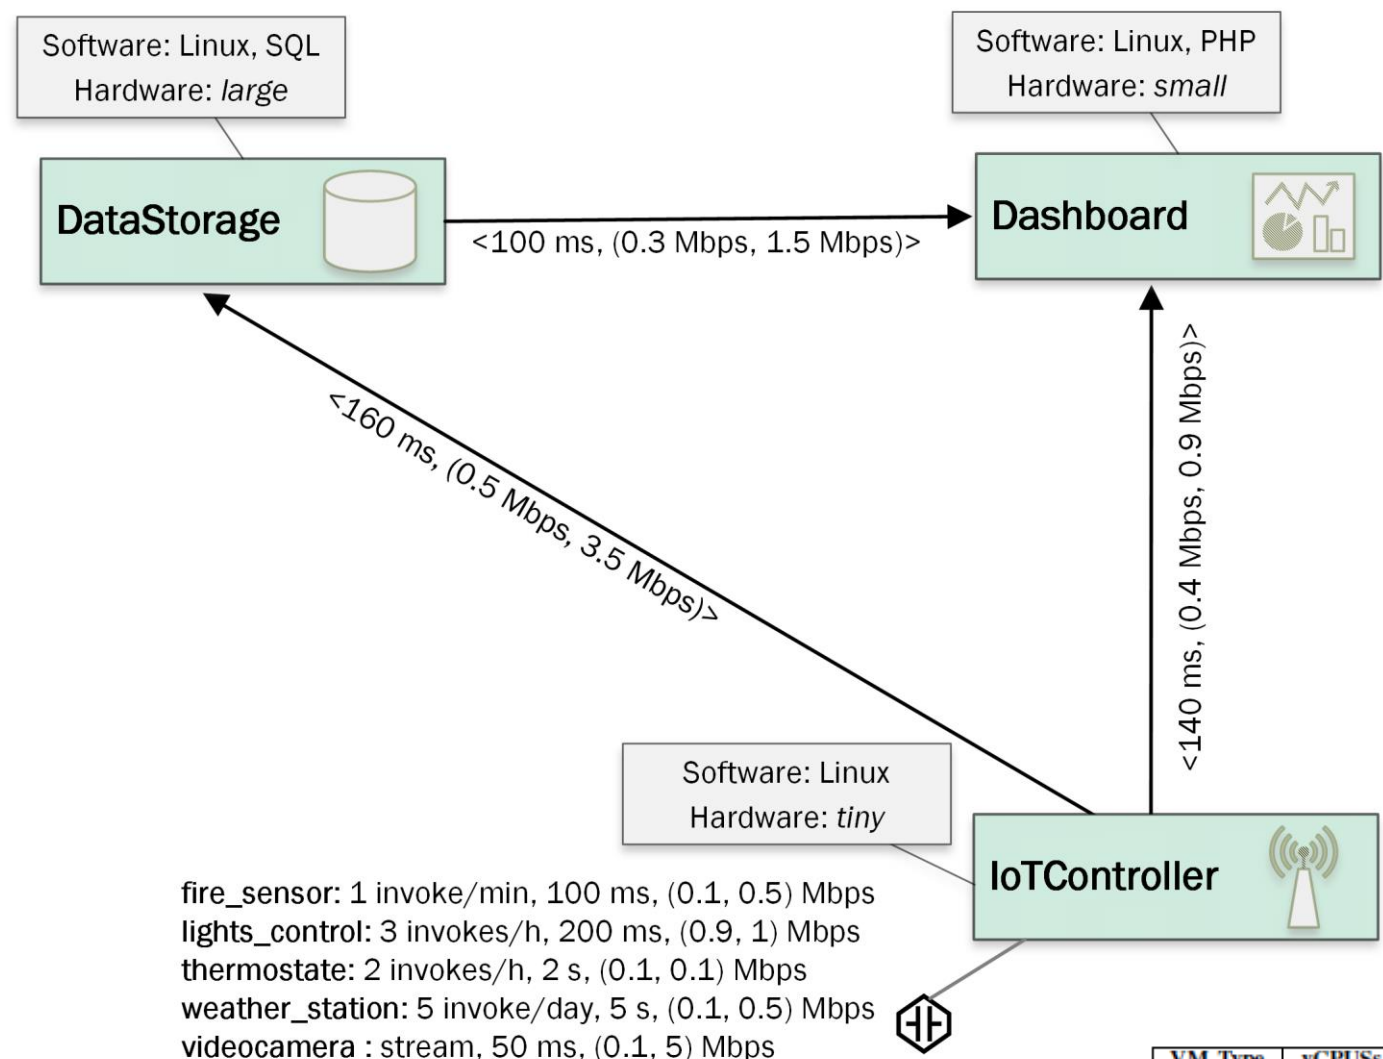

- *How many and how powerful fog nodes do I need to **adequately deploy** my application?*
- *Should I deploy this component on the **cloud**, on the **fog-as-a-service** available in my city or on my **premises gateway**?*
- *Is there any component I should better deploy on a different node after this **link/node failure**?*
- *Which are the eligible deployments that **comply most** with the required **qos**?*
- *Can I **reduce** resource consumption of some fog nodes, or **avoid** using them?*
- *Do I need to **upgrade** my infrastructure if the application requirements change?*
- ...

One **stakeholder** can play more than one **role**:

- DevOps: roles of application producer and administrator collapse
- Telecom provider providing IoT+Fog+Cloud infrastructure to its customers, and managing apps and services over the very same infrastructure
- User can act as infrastructure provider when sharing her home router as Fog capability for application deployment

Example - Simple Fog application that manages fire alarm, heating and AC systems, interior lighting, and security cameras of a smart building.

VM Type	vCPUSs	RAM (GB)	HDD (GB)
<i>tiny</i>	1	1	10
<i>small</i>	1	2	20
<i>medium</i>	2	4	40
<i>large</i>	4	8	80
<i>xlarge</i>	8	16	160

Example (cont.) – Available Fog infrastructure.

Hardware	resource	monthly cost

Example - Simple Fog application that manages fire alarm, heating and AC systems, interior lighting, and security cameras of a smart building.

The diagram illustrates a Simple Fog application architecture. It consists of three main components: DataStorage, Dashboard, and IoTController.

- DataStorage:** Software: Linux, SQL; Hardware: large. It is connected to the Dashboard with a latency of <100 ms, (0.3 Mbps, 1.5 Mbps).
- Dashboard:** Software: Linux, PHP; Hardware: small. It is connected to the IoTController with a latency of <140 ms, (0.4 Mbps, 0.9 Mbps).
- IoTController:** Software: Linux; Hardware: tiny. It is connected to the DataStorage with a latency of <160 ms, (0.5 Mbps, 3.5 Mbps).

Below the IoTController, a list of sensors and their invocation rates is provided:

- fire_sensor: 1 invoke/min, 100 ms, (0.1, 0.5) Mbps
- lights_control: 3 invokes/h, 200 ms, (0.9, 1) Mbps
- thermostat: 2 invokes/h, 2 s, (0.1, 0.1) Mbps
- weather_station: 5 invoke/day, 5 s, (0.1, 0.5) Mbps
- videocamera : stream, 50 ms, (0.1, 5) Mbps

A table titled "VM Type" is also present, showing the resource requirements for different virtual machine types:

VM Type	CPU%	RAM (GB)	HDD (GB)
tiny	1	1	10
small	1	2	20
medium	2	4	40
large	4	8	80
xlarge	8	16	160

Example (cont.) – Available Fog infrastructure.

The diagram illustrates the available fog infrastructure, showing three fog nodes (Fog 1, Fog 2, Fog 3) and two clouds (Cloud 1, Cloud 2). Each fog node has a resource table and a list of services with their costs. Fog 1 and Fog 2 are highlighted with a red dashed box.

resource	monthly cost
CPU	€ 4.0 / core
RAM	€ 3.0 / GB
HDD	€ 3.0 / GB

Example (cont.) – Questions:

- Q1 - Is there any eligible deployment of the application reaching the needed Things at Fog 1 and Fog 3, and meeting the financial (at most 850 euros/month) and QoS-assurance (at least 98% of the time) constraints?
- Q2 - Which eligible deployments minimise resource consumption in the Fog layer so to permit future deployment of services and sales of virtual instances to other customers?
- Q3 - Would there be any deployment that complies with all previous requirements and reduces financial cost and/or consumed Fog resources when upgrading from 3G to 4G at Fog 2?

- How to decide *where* to «best» deploy each component of an application by exploiting QoS-, location-, and context-awareness?
- How to estimate the «goodness» of a candidate deployment?
- Especially challenging for mission-critical applications where
 - unpredictable performances cannot be tolerated
 - limited availability of resources of Fog devices make the management of application deployments intrinsically complex

Need of **tools** helping to trade-off orthogonal dimensions

Δ15	Fog 2	Cloud 1	Cloud 2
Δ16	Fog 2	Cloud 1	Cloud 1
Δ17	Fog 2	Cloud 1	Fog 1

Five output deployments satisfy the QoS and budget constraints imposed by the system integrators. 3, 4, 7 and 10 all feature 100% QoS-assurance

- Among them, 7 is the cheapest in terms of cost, consuming as much Fog resources as 4 and 10, although more with respect to 3
- On the other hand, 2, still showing QoS-assurance above 98% and consuming as much Fog resources as 3, can be a good compromise at the cheapest monthly cost of e800

Example (cont.) – Questions:

- Q3 - Would there be any deployment that complies with all previous requirements and reduces financial cost and/or consumed Fog resources when upgrading from 3G to 4G at Fog 2?

We change the Internet access at Fog 2 from 3G to 4G. This increases the monthly expenses by e20. FogTorch now reveals six new eligible deployments in addition to the previous output. Among those, only 16 turns out to meet also the QoS and budget constraints that the system integrators require. Interestingly, 16 costs e70 less than the best candidate for Q1 (2), whilst sensibly reducing Fog resource consumption. Hence, overall, the change from 3G to 4G would lead to an estimated monthly saving of e50 with 16 with respect to 2.

Fog computing?

Deploying apps through the Fog

Concluding remarks

- Growing industrial and academic interest on fog computing (hype?)
- Various open challenges:
 - Privacy and security
 - Faults
 - Mobility
 - (standardization of) F2F, F2C, F2T interfaces
 - Testbeds

• Business models

Through the Fog

University project aiming at devising new models and techniques to deploy existing applications over the fog, to program new fog applications and to support **fog computing**.
